Abstract

N-Acetylgalactosamine-glycosylated vitamin D binding protein (GalNAc-DBP) is known to stimulate macrophages and to directly inhibit angiogenesis and cancer cell growth in vitro [4]. In this study, we evaluated the direct effect of GalNAc-DBP complexed with oleic acid on human multiple myeloma and Hodgkin’s lymphoma cell lines (KMS-12-BM and L540 respectively) as well as the effect, on the same cell lines, of human spleen macrophages (CRL9853) previously activated by GalNAc-DBP complexed with oleic acid.

Cell viability and living cell number were evaluated respectively by Tetrazolium dye cell viability assay and by Trypan Blue staining. Interactions between activated macrophages and cancer cells were studied by time lapse photography. Our results show that GalNAc-DBP complexed with oleic acid inhibits the proliferation of myeloma and Hodgkin’s lymphoma cells in a dose-dependent manner. Furthermore, GalNAc-DBP complexed with oleic acid activates human spleen macrophages which in turn phagocytise cancer cells. In addition, we observed that GalNAc-DBP complexed with oleic acid activates human spleen macrophages in vivo as documented by color-doppler ultrasonography of the spleen. These results demonstrate that GalNAc-DBP complexed with oleic acid has a double effect on myeloma and Hodgkin’s lymphoma cancer cells: a direct inhibition of their proliferation and viability and, at the same time, an efficient macrophage activation leading to a significant depletion of cancer cell population. Taken together, these results suggest that GalNAc-DBP complexed with oleic acid may prove effective in the integrative immunotherapy of multiple myeloma and Hodgkin’s lymphoma.

Abbreviations: DBP: Vitamin D Binding Protein, FBS: Foetal Bovine Serum, Gal: Galactose, GalNAc-DBP: N-Acetylgalactosamine-Glycosylated Vitamin D Binding Protein, GalNAc: N-Acetylgalactosamine, IDD: Intrinsically Disordered Domains, MAF: Macrophage Activating Factor, NO: Nitric Oxide, Sia: Sialic Acid

Introduction

In recent years the interest in the effects of vitamin D and other nutritional factors such as oleic acid in the integrative treatment of multiple myeloma and Hodgkin’s lymphoma has increased [1]. Thus, these cancers are considered calcium and vitamin D sensitive, and it has been suggested that combined supplementation may be required for optimal chemoprevention [2]. Oleic acid, on the other hand, has been known for centuries for its anti-cancer properties and, according to a recent review “The beneficial effects of oleic acid in cancer processes can no longer be doubted” [3].

It has been known since 1988 that oleic acid is non-covalently bound to the vitamin D binding protein (DBP) that constitutes one of its carrier proteins in plasma and other biological fluids [4]. We recently elucidated the molecular interactions between oleic acid, vitamin D, DBP and the vitamin D receptor [5]. In this context, it is worth noting that the anti-cancer effects of oleic acid are mediated by its interaction with proteins that are found in biological fluids such as milk or plasma [6]. Therefore, it can be hypothesized that DBP, by virtue of its complexing with oleic acid, may play a role in anti-cancer immune-surveillance that goes beyond that of a carrier protein.

DBP is encoded by a gene located on 4q12-q13 (HGNC:4187), and it is also known as group-specific component (GC). DBP exists in different isoforms and the one designated Gc1s is glycosylated and comprises a linear O-linked trisaccharide of the type GalNAc-Gal-Sia attached to the threonine residue at position 420 [7]. During immune responses and in milk fermentation, sialic acid and galactose are enzymatically removed, and the Gc1s isoform of DBP with the remaining GalNAc covalently bound to threonine 420 is known to stimulate macrophages [8].

In addition to this effect on macrophage function, GalNAc-DBP, sometimes also designated DBP-MAF by some Authors (Macrophage Activating Factor) is known to directly inhibit tumour angiogenesis and human prostate and breast cancer cell proliferation in vitro [9-11].

Consistent with these observations, we previously demonstrated that GalNAc-DBP stimulated Raw 264.7 cells (a murine macrophage cell line) that were observed in vitro to phagocytise MCF-7 cells (human breast cancer cells) [12].

breast carcinoma cells) [5]. In those studies, however, GalNAc-DBP was used as an isolated, purified protein that is non-complexed with oleic acid as it occurs in physiological conditions. In addition, those results were obtained in a co-culture of activated murine macrophages and human breast cancer cells, and thus they could not be directly extrapolated to the conditions occurring in human neoplasia.

Therefore, we decided to study the effects of GalNAc-DBP complexed with oleic acid on human multiple myeloma (KMS-12-BM) and Hodgkin’s lymphoma (L540) cells as well as the effect, on the same cells, of human spleen macrophages (CRL9853) previously activated by GalNAc-DBP complexed with oleic acid.

We also studied the activation of spleen macrophages in vivo taking advantage of the recently published observation that macrophages activated by GalNAc-DBP complexed with oleic acid release the vasodilating molecule nitric oxide (NO), thus allowing for direct visualization of increased blood flow in the spleen through color-doppler ultrasonography [12].

**Materials and methods**

**Cell lines**

KMS-12-BM; L540: Human multiple myeloma (KMS-12-BM), and human Hodgkin’s lymphoma (L540) cell lines were purchased from DSMZ (German Collection of Microorganisms and Cell Cultures, Braunschweig, Germany), and cultured in RPMI 1640 supplemented with 10% FBS and 2mM L-Glutamine (Life Technologies, Paisley, UK). Cultures were passaged every 3-4 days.

CRL9853: Human spleen macrophage was purchased from ATCC (American Type Culture Collection, Teddington, UK) and routinely cultured in IMDM supplemented with 10% FBS and 2mM L-Glutamine (Life Technologies, Paisley, UK). Cultures were passaged every 3-4 days. Prior to assay, CRL9853 cells were activated cultivating them for 72h in the presence of GalNAc-DBP complexed with oleic acid at a concentration 100ng/mL in complete medium.

**Stimuli**

GalNAc-DBP complexed with oleic acid, commercially available, was prepared at Immuno Biotech Ltd (Guernsey, Channel Island, GBG) with a procedure previously described [12]. A the end of the preparation, GalNAc-DBP complexed with oleic acid was analyzed at Macro with a procedure previously described [12]. At the end of the preparation, the medium was replaced with 100μl of fresh starvation medium plus 10μl of WST-8. The 96 well plate was incubated for 3h at 37°C and the optical density (O.D.) was directly measured at A<sub>450nm</sub> by Multiscan FC photometer (ThermoScientific, Milano, Italy).

**Cell proliferation assay**

Cell proliferation and viability were evaluated by the reduction of a Tetrazolium salt (WST-8) as an index of cell dehydrogenases’ activity. KMS-12-BM and L540 cells were seeded into a 96 wells plate at a density of 3x10<sup>4</sup> cells/well in their appropriate starvation medium (without FBS). After incubation for 24h the cell lines were treated for 24h with the following different concentrations of GalNAc-DBP complexed with oleic acid [8-80-800 pM]. At the end of the treatment, the medium was replaced with 100μl of fresh starvation medium plus 10μl of WST-8. The 96 well plate was incubated for 3h at 37°C and the optical density (O.D.) was directly measured at A<sub>450nm</sub> by Multiscan FC photometer (ThermoScientific, Milano, Italy).

**Cell counting – trypan blue assay**

To corroborate the results obtained by the cell proliferation and viability assay, a viable cell count was performed. Briefly, KMS-12-BM and L540 cells were plated into 6 wells plate at a density of 2x10<sup>4</sup> cells/well in starvation medium. After 24h incubation, cells were treated with GalNAc-DBP complexed with oleic acid at the increasing concentrations [8-80-800 pM] for 24h. At the end of the treatment, a volume of cell suspension was collected and the viable cell number was counted by Trypan Blue staining.

**Video time-lapse photography**

KMS-12-BM and L540 cells were seeded into a 24 wells plate at a density of 1x10<sup>4</sup> cells/well with a 1mL volume. The cells were allowed to settle for a minimum of 2h prior to the addition of the CRL9853 macrophages that had been previously activated by GalNAc-DBP complexed with oleic acid. The staging mat was set at a temperature of 37°C and allowed to equilibrate prior to placement of the 24 wells plate (Figure 1).

The activated CRL9853 human spleen macrophages were added to a final concentration of 5x10<sup>6</sup> cells per well in 1mL. HEPES (Fisher Scientific, Loughborough, UK) was added to each well to provide a final concentration of 25mM to stabilize the culture pH. Once activated macrophages and the HEPES were added, the 24wells plate was observed microscopically and an image selected. An initial frame was taken and a time-lapse film initiated. A frame was taken every 3 minutes until filming was stopped.

Results

Cell proliferation assay

Cell proliferation and viability of KMS-12-BM human multiple myeloma cells (Figure 2), evaluated both by Tetrazolium dye cell assay (Figure 2A) and by Trypan Blue staining (Figure 2B), decreased when the cells were treated with increasing concentrations of GalNAc-DBP complexed with oleic acid. In particular, when cells were treated with GalNAc-DBP complexed with oleic acid (800pM) a significant reduction (p<0.01) in cell viability was observed in comparison to the untreated control cells.

Qualitatively identical results were obtained with L540 human Hodgkin’s lymphoma cells (Figure 3, panels A and B). Inhibition of cell proliferation and viability by GalNAc-DBP complexed with oleic acid was even more pronounced than that observed in human multiple myeloma cells.

Video time-lapse photography

Figure 4, shows selected frame shots over time of KMS-12-BM cells in the presence of CRL9853 human spleen macrophages that had been previously activated by GalNAc-DBP complexed with oleic acid under the conditions described in “Materials and Methods” and shown in Figure 1. Panel A, shows KMS-12-BM suspension culture typical growth pattern. Panel B, shows KMS-12-BM cells 24h post addition of activated macrophages. CRL9853 spleen macrophages cultures appear as large masses of suspension cells and the dense collection of cells can be observed sitting on the KMS-12-BM suspension cells. The activated macrophages are extremely motile under observation and move around clearing the KMS-12-BM cells. During the phagocytosis, smaller dense “clusters” of cells break off and scavenge the KMS-12-BM cells quite...
rapidly. Panel C, shows KMS-12-BM cells 48h post addition of activated human macrophages. CRL.9853 cells now have a few large cell mass “clusters” and many smaller “clusters” as can be observed (red arrows). The number of KMS-12-BM cells has been decreased and the clearance of cells can be easily observed. Finally, panel D, shows KMS-12-BM cells 72h post addition of activated human macrophages CRL.9853. Activated CRL.9853 cells are still extremely active with the phagocytic activity and are clearing the KMS-12-BM cells from the culture. This image shows the smaller clusters of cells as indicated by the red arrows. The clusters have become smaller and rapid moving seeking out and destroying the remaining KMS-12-BM cells. Qualitatively identical results were obtained with L540 human Hodgkin’s lymphoma cells (not shown).

**Ultrasonography of the spleen and activation of spleen macrophages in vivo**

Since the results described above indicate that human spleen macrophages were activated by GalNAc-DBP complexed with oleic acid *in vitro*, we decided to study whether a comparable activation could be observed *in vivo*. To this end, we exploited the fact that activated macrophages release NO [13]. Considering the impressive effects of NO in pre-clinical models of cancer where it slows tumour growth and enhances the efficacy of both chemotherapy and radiotherapy [15], we reasoned that the observation of activation of spleen macrophages *in vivo* could further corroborate the hypothesis of proposing GalNAc-DBP complexed with oleic acid as an integrative immunotherapeutic agent.

Therefore, we opted to study the variation of the splenic blood flow, following the administration of GalNAc-DBP complexed with oleic acid (880ng, dissolved in 5mL saline) by nebulisation. According to our hypothesis, GalNAc-DBP complexed with oleic acid would be absorbed into the bloodstream and it would stimulate the huge amount of macrophages residing in the spleen [16]. Therefore, we would expect a significant release of NO by activated macrophages in this organ, with consequent vasodilation and increase of blood flow that we could measure by color-doppler ultrasonography.

One of us (MR), self-administered GalNAc-DBP complexed with oleic acid (880ng, dissolved in 5mL saline) by nebulisation for about 5 min. After that, the subject, who is an expert radiologist, self-examined his spleen with color-doppler ultrasonography.

Figure 5, panels A and B, shows the ultrasonographic appearance of the spleen of the volunteer before nebulisation; morphology, size and ultrasonographic structure appear normal. The splenic blood flow could be appreciated in correspondence of the hilum of the spleen. The mean diameter of the blood vessels at the hilum was 4.4mm. Figure 5, panels C and D, shows the splicenic blood flow 15 min after nebulisation of GalNAc-DBP complexed with oleic acid. The mean diameter of the blood vessels at the hilum was 6.1mm.

During immune responses [17] and in milk and colostrum during fermentation [18,19], GalNAc-DBP, as an isolated protein, has been studied in a number of experimental models of diseases, from osteopetrosis [17] to cancer [10] and autism [20].

However, the effects of GalNAc-DBP complexed with oleic acid have never been studied in controlled experimental models. In other words, all the studies on this subject concentrated on the effects of the isolated protein and not on the overall effects of the physiological assembly of the protein with oleic acid. Therefore, in the context of a proposable integrative immunotherapeutic approach, we decided to study the effects of GalNAc-DBP complexed with its natural counterpart that is oleic acid.

In this study, we demonstrate that GalNAc-DBP complexed with oleic acid, stimulated human spleen macrophages, both *in vitro* and *in vivo* although the demonstration of macrophage activation *in vivo* was indirect. The effects of the complex GalNAc-DBP-oleic acid were significantly more pronounced when compared to the effects of GalNAc-DBP alone; oleic acid per se did not stimulate human spleen macrophages (not shown).

Human spleen macrophages that had been pre-activated by GalNAc-DBP complexed with oleic acid were able to recognize and phagocytize human cancer cells *i.e.* multiple myeloma and Hodgkin’s lymphoma cells.

However, GalNAc-DBP complexed with oleic acid, in addition to this effects involving activation of tumoricidal macrophages, also exerted a direct effect on human myeloma and Hodgkin’s lymphoma cells cultures, and it inhibited their proliferation and viability. These results are consistent with those previously reported by Gregory...
et al. and by Pacini et al. on human prostate and breast cancer cells respectively [10,11].

We hypothesize that the multitude of biological effects exerted by this protein when associated with oleic acid can be explained by the recent discovery of the so-called “Intrinsically Disordered Domains” (IDDs). It is now widely recognized that proteins withIDDs are found in organisms from all kingdoms of life and, in eukaryotes, they perform a wide range of biological functions, including regulation and signaling [21]. These domains lack a fixed or ordered three-dimensional structure and cover a spectrum of states from fully unstructured to partially structured that may include random coils, molten globules, and large multiple domains connected by flexible linkers. Their mobile flexibility and structural instability are encoded by their amino acid sequences [22].

Thus, IDDs are characterized by the presence of hydrophobic amino acids interspersed with positively and negatively charged amino acids. Therefore these domains cannot bury sufficient hydrophobic core to fold like stable globular proteins [23]. However, when a bulky hydrophobic moiety, such as the molecule of oleic acid, binds to a protein region where an IDD is present, the molecular configuration of the IDD changes dramatically together with the specificity of interaction with other target molecules.

Using disorder prediction algorithms based on primary sequence composition, we identified two IDDs in the GalNAc-DBP (Figure 6) and, interestingly, one of these IDD, designated IDD2 because of its position in the amino acid sequence, is in the same region where oleic acid binds. The shallow hydrophobic cleft where oleic acid binds is located between domains II and III, which is between positions 288 and 371, thus encompassing the IDD2 that is located between positions 298-325.

Therefore, we hypothesize that the multifarious effects of this protein, in particular when it is complexed with its natural counterpart that is oleic acid, are due to the presence of this peculiar IDD2 modified by the non-covalent binding with a hydrophobic molecule such as oleic acid.

This finding could be of particular interest in the context of an integrated immunotherapy of cancer based on molecular structures. For example, one of the major human oncogenes, myc, encodes an intrinsically disordered protein that can be bound and inhibited by small molecules through formation of dynamic complexes [21].

Therefore, it can be hypothesized that GalNAc-DBP complexed with oleic acid binds Myc (and/or other products of oncogenes or tumour suppressor genes), thus countering the effects of the oncoprotein at the molecular level. The presence of positively and negatively charged amino acids in the proximity of the oleic acid binding renders the molecular complex highly dynamic, thus favouring the interaction with multiple target proteins, such as Myc or p53, that exhibit similar IDDs [24].
